Mnemonic use for aiding students to determine erythro vs threo stereochemistry in additions to internal alkenes

Abstract:

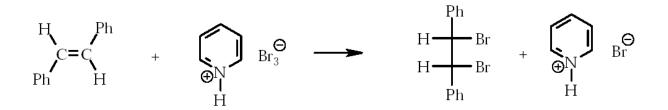

Use of the <u>TOES</u> mnemonic allows organic chemistry students to quickly write the correct Fischer projections and erythro vs threo nomenclature for additions to the double bonds of internal alkenes.

Many organic chemistry students have great difficulty visualizing stereochemistry or predicting outcomes on paper based upon Fischer projections or wedge and dot format. In particular, determining erythro vs threo stereochemistry for adducts of cis or trans alkenes with reagents adding cis or trans is troublesome. Even for those who can write the Fischer projection correctly, many are confused as to whether it represents erythro or threo. I have found that use of the <u>TOES</u> minemonic clears the confusion and always gives correct answers

both for Fischer projections and erythro vs threo nomenclature. Students easily remember TOES. Just think "what is on your feet besides shoes and socks", or "what are at the front of your feet"? In this mneomic, T = opposite, where T represents three parameters 1, configuration of the alkene versus mode of addition, <u>2</u>, orientation of the added group in the resulting Fischer projection, and 3, threo. For example, trans cinnamic acid adds 2 OH groups cis on reaction with osmium tetroxide., which is opposite, and the resulting two Fischer projection have the two OH groups opposite, and the nomenclature is threo. In this mneomic, E = same. For example, trans cinnamic acid adds bromine trans, which is the same, and the resulting two Fischer projections have the two Br groups on the same side, and the nomenclature is erythro. See the example below for trans cinnamic acid adding trans with bromine (same), yielding dibromide enantiomers on the same side with erythro nomenclature

If the alkene has two identical groups on the double bond and the mode of addition is the <u>s</u>ame as the alkene configuration, the mnemonic predicts <u>e</u>rythro nomenclature, with both adding groups on <u>s</u>ame side in the Fischer projection. While technically correct, the student has learned that enantiomers with an internal plane of symmetry are actually a single MESO form. See the reaction below giving MESO dibromostilbene from <u>t</u>rans bromination of <u>t</u>rans stilbene with pyridinium bromide perbromide.

<u>Table-1</u> lists all possible combinations using this mnemonic.
